Assignment 6

Problem Statement : ARP Poisoning Detection

ARP (Address Resolution Protocol) poisoning, also known as ARP spoofing, is a type of attack where an attacker sends falsified ARP reply messages over a local area network to link the attacker's MAC address with the IP address of another host (usually the default gateway). This allows the attacker to intercept, modify, or redirect network traffic intended for the target host.

In this exercise, you need to write a Python program to detect ARP poisoning attacks on the local network using scapy library. The program will continuously sniff ARP packets and compare the MAC addresses of the sender's IP with the one obtained from the system's ARP cache (ARP table). If a mismatch is found, it indicates the possibility of an ARP poisoning attack.

Design of the solution : Two programs are designed for this problem.

- 1) Detection : Simply by running 'arp -a', the ARP table input of the system is captured, the data is processed and stored into a dictionary {'ip' : 'mac'}. Then the program is checking arp packets. If it gets any, it goes through the dictionary and checks if the corresponding value is the same or not. If mismatch found, ARP spoofing/poison reported
- 2) Attack : Getting target ip and gateway ip (router ip usually) from the user, then an ARP packet is sent to know the mac address of the target machine, and then with the help of gateway ip, mimicking the gateway sender, the program spoofs ARP.

Source Code :

Detector.py

```
from scapy.all import sniff
import os

# Dictionary to hold IP to MAC address mappings
ARP_TABLE = {}
```

```

# Run 'arp -a' command to get ARP table information
output = os.popen('arp -a').read()
output = output.split('\n')
output = output[3:-1]
# Parse the output and populate the ARP_TABLE dictionary
for line in output:
    line = line.split()
    ARP_TABLE[line[0]] = line[1].replace('-', ':')
print(ARP_TABLE)
# Print headers for output
print('Source', '\t', 'HW_Source', '\t', 'Status')

# Function to detect ARP spoofing
def detect(packet):
    Source = packet['ARP'].psrc
    HW_Source = packet['ARP'].hwsrc

    # Check if the source IP is in the ARP_TABLE
    if Source in ARP_TABLE:
        # If the MAC address for the IP has changed, it might indicate ARP
        # spoofing
        if ARP_TABLE[Source] != HW_Source:
            print(Source, HW_Source, 'ARP Spoofing Detected')
        else:
            print(Source, HW_Source, 'Seems Legit')
    else:
        # If a new device is detected, add it to the ARP_TABLE
        print(Source, HW_Source, 'New Device Detected')
        ARP_TABLE[Source] = HW_Source

# Continuously sniff ARP packets and call the detect function
while True:
    sniff(prn=detect, filter='arp', count=1)

```

Attacker.py

```
import time
```

```

from scapy.all import ARP, Ether, srp, send

# Function to retrieve MAC address given an IP address
def retMac(IP):
    # Create an ARP packet with the given IP as the destination
    ARP_Packet = ARP(pdst=IP)

Assignment 7

Traceroute Implementation

Traceroute is a network diagnostic tool used to track the route that packets take from the source to a destination. It sends packets with increasing Time-to-Live (TTL) values and observes the ICMP “Time Exceeded” responses from intermediate routers. Scapy allows you to implement traceroute easily by sending ICMP packets with varying TTL values and analyzing the responses.

- Write a Python program that implements the traceroute functionality using Scapy.
- The program should take a destination IP address as input and send a series of ICMP packets with varying Time-to-Live (TTL) values to trace the route to the destination.
- Display the IP addresses of the routers along the path.

In your code, define a function `traceroute()` that takes the destination IP address and the maximum number of hops as inputs. Run a loop from TTL 1 to max hops, creating ICMP echo request packets with the corresponding TTL values and sending them using `sr1()` (send and receive in one function) from Scapy. Consider a timeout period of 1 second for the response.

- If you receive no response within the timeout, we print `*` to indicate no response from that hop.
- If you receive an ICMP Echo Reply, it means we have reached the destination, and we print the destination IP address.
- If you receive an ICMP Time Exceeded, it indicates that the packet has reached an intermediate router, and we print the router’s IP address.

Please note that the actual number of hops may be less than max hops, depending on the network topology and firewall configurations. Also, some routers might be configured to not respond to ICMP Time Exceeded messages, which can result in incomplete traceroute information.

Design of the solution : Sending a ICMP dummy message to the user given destination ip for the maximum of hops that will be taken from the user. Every dummy message we send in a loop will be incremental of TTL value. If we receive a ICMP echo reply we will break the loop and print destination reached, if we do not get any echo reply throughout the loop, we will print destination unreachable. And most importantly, in every iteration we will print the end node where the packet is discarded/received(as TTL value goes to zero).

Source Code :

TRACERT.py

```
from scapy.all import sr1, ICMP, IP

# Function to perform traceroute
def traceroute(URL, MAX_HOPS):
    SUCCESS = False # Flag to track successful reach to destination
    # Iterate through TTL values from 1 to MAX_HOPS
    for TTL in range(1, MAX_HOPS+1):
        # Create an ICMP packet with increasing TTL to trace the route
        Packet = IP(dst=URL, ttl=TTL) / ICMP() / 'Hello World'
        # Send the packet and wait for a reply (1 second timeout)
        Reply = sr1(Packet, verbose=False, timeout=1)

        # Check the reply
        if Reply is None:
            # No reply received within the timeout, print '* * *'
            print('TTL: ', TTL, ' * * *')
        elif Reply.type == 0: # ICMP Echo Reply received (destination
reached)
            # Print the TTL and the source IP
            print('TTL: ', TTL, ' ', Reply.src)
            print('Reached Destination')
            SUCCESS = True # Set success flag to True
            break # Exit the loop, destination reached
        else:
            # Intermediate hop reached, print the TTL and source IP
            print('TTL: ', TTL, ' ', Reply.src)
```

```

# If destination not reached, print 'Destination Unreachable'
if not SUCCESS:
    print('Destination Unreachable')

# Input URL and maximum hops
URL = input('Enter URL: ')
MAX_HOPS = int(input('Enter Max Hops: '))
traceroute(URL, MAX_HOPS) # Call the traceroute function

```

Sample Run :

This is a sample run where the destination is unreachable.

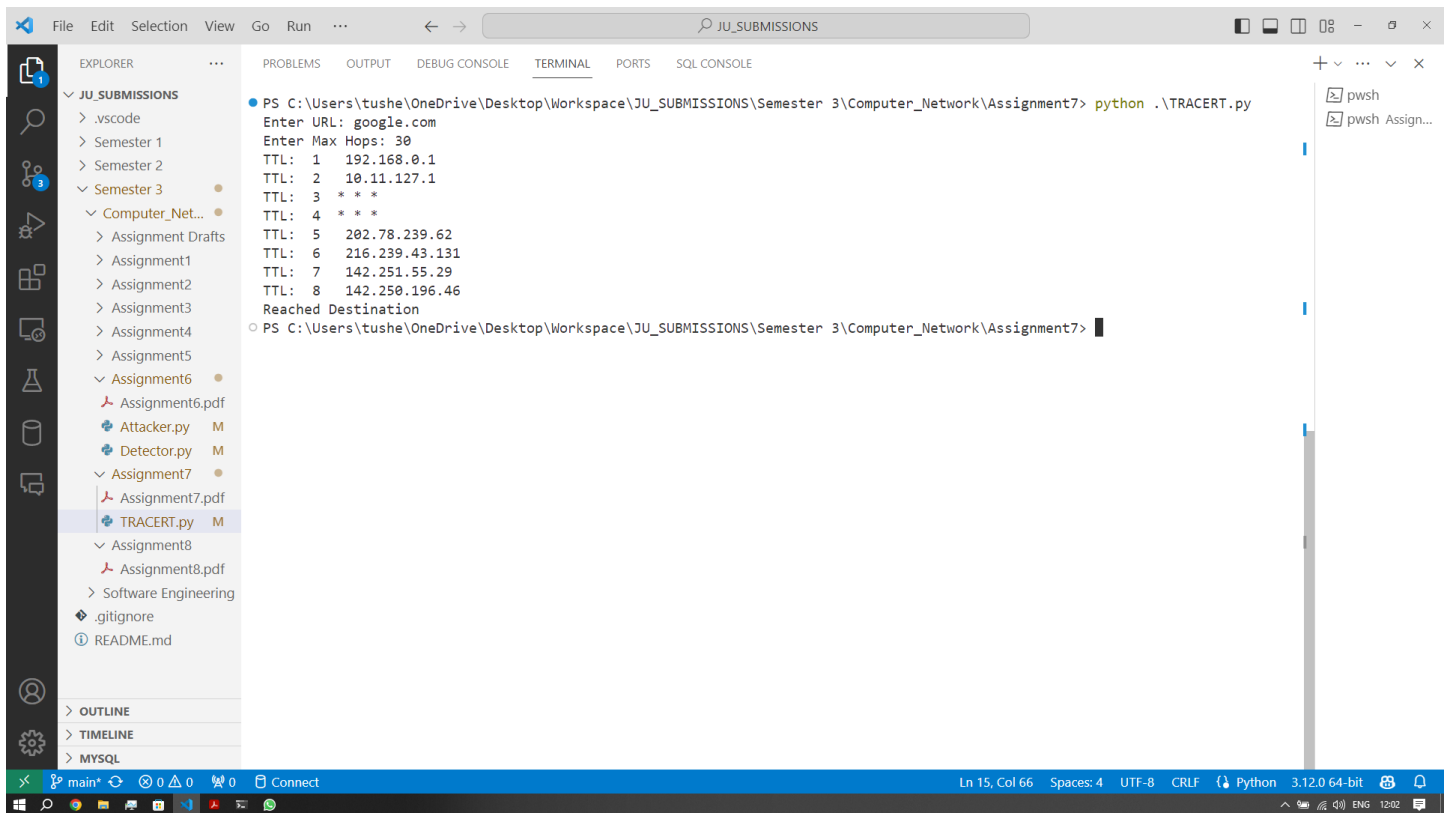

The screenshot shows a VS Code editor with a terminal window open. The terminal displays the output of a Python script named TRACERT.py. The script prompts the user to enter a URL and a maximum number of hops. The user enters 'jadavpuruniversity.in' and '30'. The script then performs a traceroute, displaying the results for each hop. The output shows 30 hops, with the final destination being unreachable.

```

PS C:\Users\tushe\OneDrive\Desktop\Workspace\JU_SUBMISSIONS\Semester 3\Computer_Network\Assignment7> python .\TRACERT.py

```

This is a sample run where the destination is reached.

The screenshot shows a Visual Studio Code editor with a terminal window open. The terminal displays the output of a Python script named `TRACERT.py` being executed in a PowerShell prompt. The script performs a traceroute to `google.com` with a maximum of 30 hops. The output shows the path taken, with the final hop reaching the destination IP `142.250.196.46`. The Explorer sidebar on the left shows the project structure, including folders for Semesters 1, 2, and 3, and a subfolder for Computer Networks containing Assignment Drafts and Assignments 1 through 8. The file `TRACERT.py` is highlighted in the Explorer. The status bar at the bottom indicates the current file is `main*` and the editor is using Python 3.12.0 64-bit.

```
PS C:\Users\tushe\OneDrive\Desktop\Workspace\JU_SUBMISSIONS\Semester 3\Computer_Network\Assignment7> python .\TRACERT.py

Assignment 8

Problem 1: Create basic LAN topologies

1. Connect two hosts back-to-back with a crossover cable. Assign IP addresses, and see whether they are able to ping each other.
2. Create a LAN (named LAN-A) with 3 hosts using a hub.
3. Create a LAN (named LAN-B) with 3 hosts using a switch. Record contents of the ARP Table of end hosts and the MAC Forwarding Table of the switch. Ping each pair of nodes. Now record the contents of the ARP Table of end hosts and the MAC Forwarding Table of the switch again.
4. Connect LAN-A and LAN-B by connecting the hub and switch using a crossover cable. Ping between each pair of hosts of LAN-A and LAN-B. Now record the contents of the ARP Table of end hosts and the MAC Forwarding Table of the switch again.

1.

The screenshot shows a 'HOST 1' window with tabs for Physical, Config, Desktop, Programming, and Attributes. The 'Desktop' tab is active, displaying a 'Command Prompt' window. The command prompt shows the execution of a ping command from 192.168.0.2, resulting in four successful replies and a 0% loss rate.

```

Problem 2: Set up VLANs and inter-VLAN routing

1. Create a LAN (named PC-LAB1) with six hosts connected via a layer-2 switch (named PC-LAB1-Switch).
2. Create two VLANs named “student” and “faculty”. Put any three hosts into VLAN “student” and other three into VLAN “faculty”
3. Create another LAN (named PC-LAB2) with six hosts connected via a layer-2 switch (named PC-LAB2-Switch).
4. Repeat Experiment 2(b) for PC-LAB2.
5. Connect the two switches via trunk ports and configure such that students/faculty in PC-LAB1 are able to communicate with students/faculty in PC-LAB2 and vice versa.

Problem 3: Create two LANs and connect them via a router

1. Create a LAN (named JU-Main) with three hosts connected via a layer-2 switch. Connect the switch to a router. Assign IP addresses to all the hosts and the router interface connected to this LAN from network address 192.168.120.0/24. Configure the default gateway of each host as the IP address of the interface of the router, which is connected to the LAN.
2. Create another LAN (named JU-SL) with three hosts connected via a layer-2 switch. Connect this switch to another router. Assign IP addresses to all the hosts and the router interface connected to this LAN from network address 192.168.130.0/24. Configure the default gateway of each host as the IP address of the interface of the router which is connected to the LAN.
3. Connect the two routers through appropriate WAN interfaces. Assign IP addresses to the WAN interfaces from network 192.168.150.0/24.
4. Add static route in both of the routers to route packets between two LANs.
5. Test the configuration by sending ping requests from hosts in each LAN.

PC5 from JU-SL is pinging to hosts from JU-MAIN

Problem 4: Configure dynamic routing using RIP

1. Create a network topology as shown above.
2. Configure all the routers to use dynamic routing protocol RIP.
3. Test your configuration by Mping each pair of hosts.
